HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Development of a new MR Elastography protocol to measure the functional properties of facial muscles

Keywords: zygomatic major; muscle tissue elasticity; Magnetic Resonance Elastography.

1. Introduction
The face expression is animated by the movements of the muscles, which can be altered during pathology. Assessment of facial muscle deficits is subjective (palpation), dependent operator, and is currently estimated with clinical scales (Kanerva et al. 2006). Thus, the quantification of the facial muscle functional properties is a key point for the clinician to adapt and evaluate treatments (surgical, injection or re-education) for patients with facial paralysis. Magnetic resonance elastography (MRE) has been developed to measure the in vivo elastic properties of healthy (Chakouch et al. 2016) and pathological (Bensamoun et al. 2015) muscles. The objective of this study is to develop a new imaging protocol to evaluate the functional properties of the zygomaticus major (ZM) muscle using MRE technique.

2. Methods
2.1 Magnetic Resonance Elastography (MRE)
MRE was conducted with a 1.5T Signa HDx MR machine (General Electric, Milwaukee, WI, USA) on three healthy participants in a supine position. To characterize the ZM muscle, in a relax state, a pneumatic driver was placed below the zygomatic bone in the direction of the corner of the mouth (Figure 1-A). This driver has a rectangular mouthpiece (1.5 cm x 2.5 cm) and is surrounded with a pad. To ensure good transducer contact, a pad was added to the top of the driver that induced no movement when the head coil (32 channels) was added. Periodic variations in air pressure were induced inside the tube at 90 Hz resulting in the propagation of acoustic waves within the facial muscles. The MRE pulse sequence included a motion-encoding gradient, that oscillated in the Z direction, was used to image the displacement of the shear waves.

2.2 Anatomical and phase images
MRI acquisition of the ZM is a challenge due to its thin morphology and long structure. In the present study, anatomical axial T1-weighted images (Figure 1-B) of the ZM were evaluated using a specific MRI protocol developed by the Radiology Department at CHU Amiens in collaboration with maxillofacial surgeons.

Then, an oblique scout was placed in the ZM to track the propagation of the shear waves. The wave displacement phase images were recorded with a 256 x 256 acquisition matrix, two opposite polarities of the motion-encoding gradient (with a 2.2 G/cm maximum amplitude limit) in the Z direction, a flip angle of 25°, a 18 cm field of view, a 1.5 mm slice thickness and 4 offsets were recorded. The scan time was 45 seconds with a TR/TE of 55.5/19.1 ms.

2.3 Phase image processing and data analyses
The recorded phase images underwent post processing by applying a mask that removed the noise located in the background of the image. A directional filter oriented along the direction of the wave propagation and a Butterworth spatial filter were applied to simultaneously remove interfering waves, longitudinal waves, and noise (Manduca et al. 2003).

Assuming that the ZM muscle was linearly elastic, isotropic, homogeneous and incompressible, the shear modulus (μ), representing the local elasticity, was calculated using the following equation: μ = ρ (f. λ)^2 where ρ is the muscle density and was assumed to be close to that of water (i.e. 1000 kg/m³), f is the frequency and λ is the wavelength.

The originality has been to develop a new MRE protocol for thin muscles (<3mm) and it remains technological challenges. The present study is the first to demonstrate the utility of MR elastography in the regular care of facial palsy patients and paves the way for other applications.
